

### Testbed for the generation of excitations and the critical velocity

type of ions:

- ▶ electrons ( $-$ ) : zero-point motion  $\longrightarrow$  bubbles  $r = 19 \text{ \AA}$
- ▶  $^4\text{He}^+$ ,  $\text{H}_2^+$  ( $+$ ) : attract He atoms  $\longrightarrow$  snowballs  $r \approx 7 \text{ \AA}$
- ▶ other ions ( $-$ ,  $+$ ) : properties depend on wave function

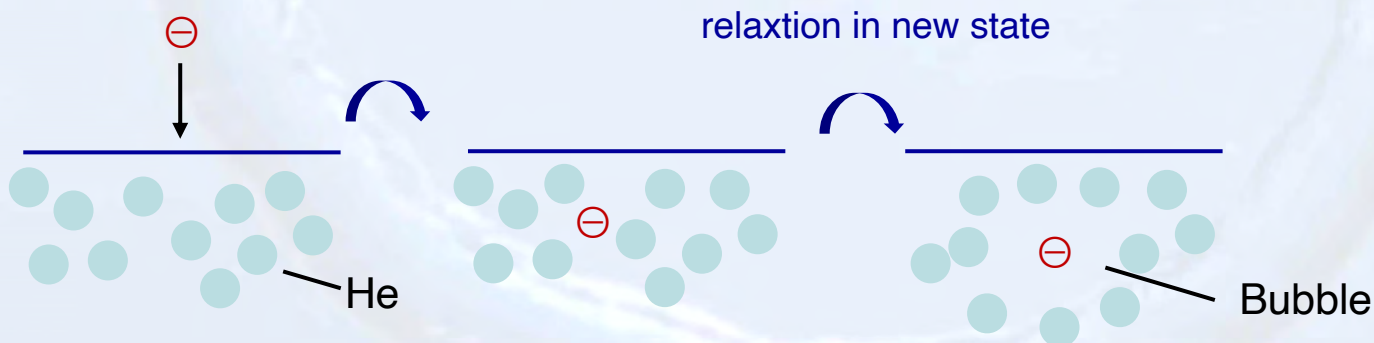

### Electrons in liquid He

electrons need energy to be emerged in helium  $\sim 1 \text{ eV}$ , which means they need more than  $1 \text{ eV}$  of kinetic energy to enter liquid He.

comment:

similar to work function of electrons in metals

bubble formation

### Energy of bubble

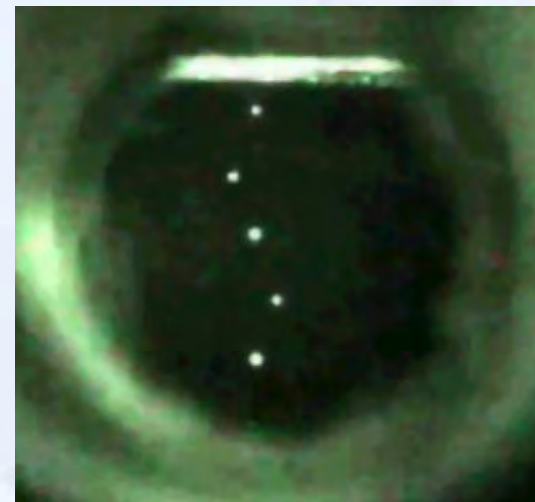

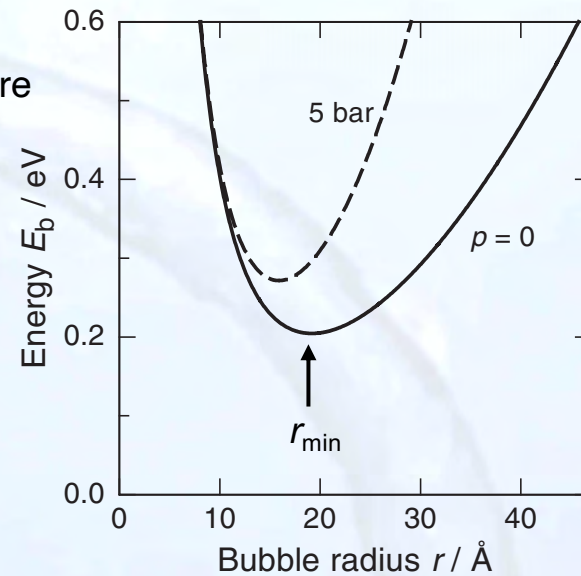

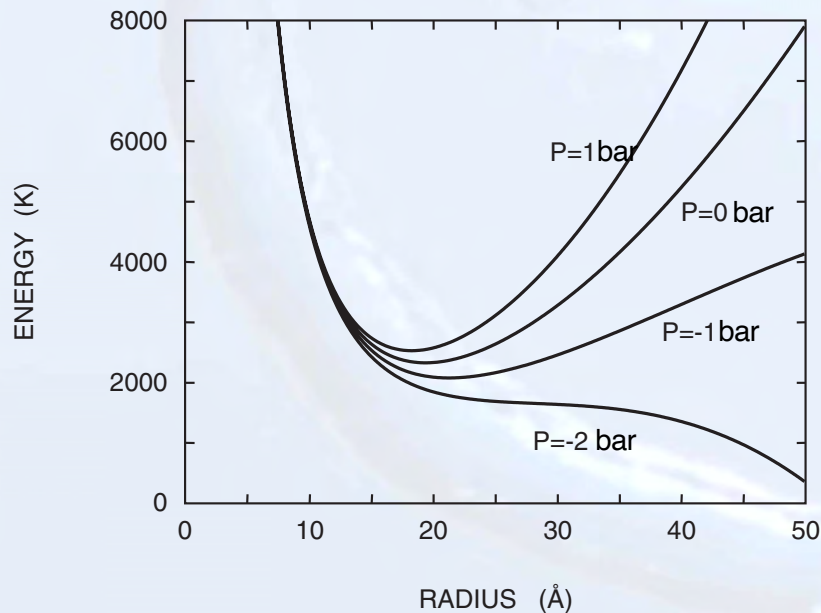

$$E_b = \underbrace{\frac{h^2}{8mr^2}}_{\text{zero-point energy}} + \underbrace{4\pi r^2 \alpha}_{\text{surface tension}} + \underbrace{\frac{4}{3}\pi r^3 p}_{\text{volume}} \quad \text{applied pressure}$$

$\alpha = 3.41 \text{ } \mu\text{J}/\text{cm}^2$

### bubble size:

$$\frac{\partial E}{\partial r} = 0 \longrightarrow r_{\min}(p=0) = 19 \text{ } \text{\AA}$$

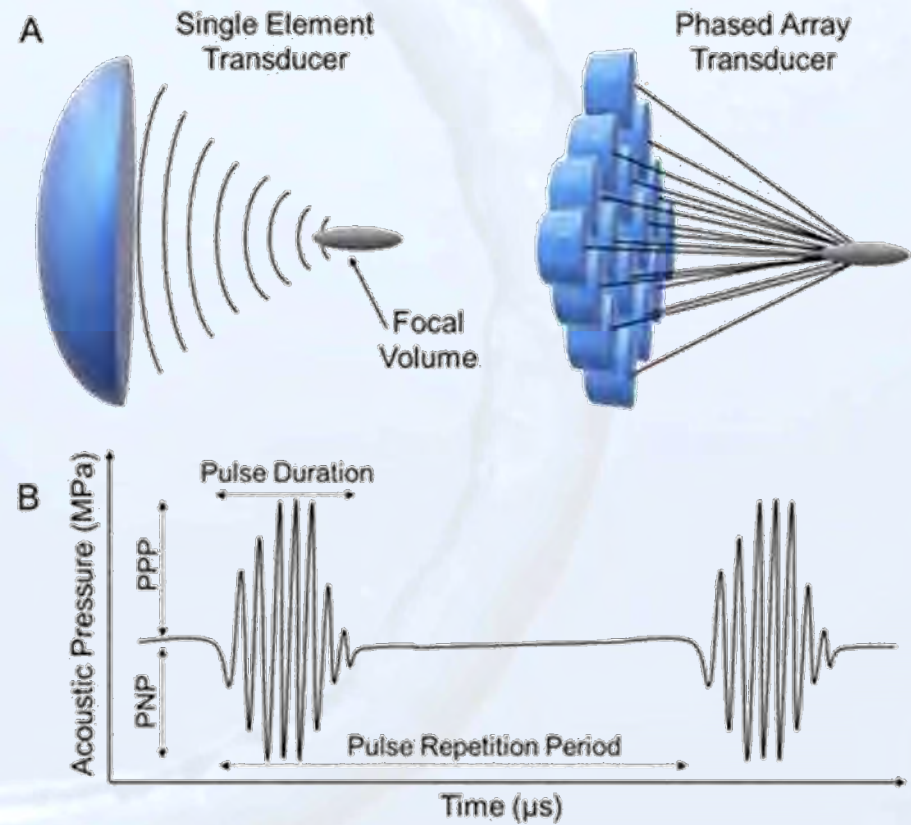

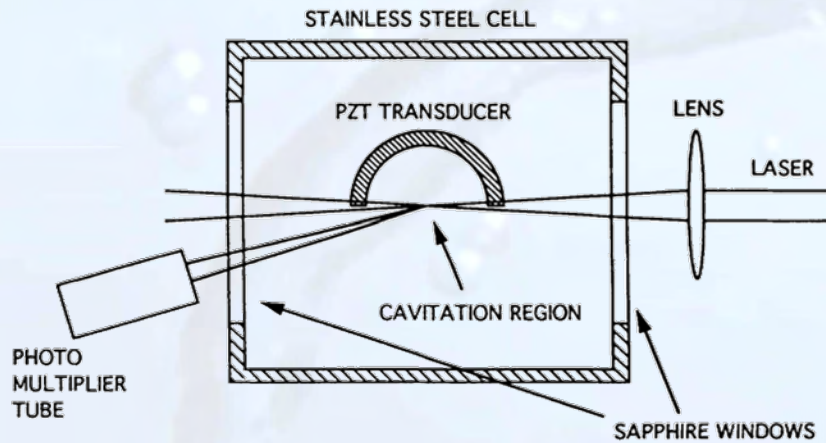

### size depends on pressure

exploding bubbles at negative pressure

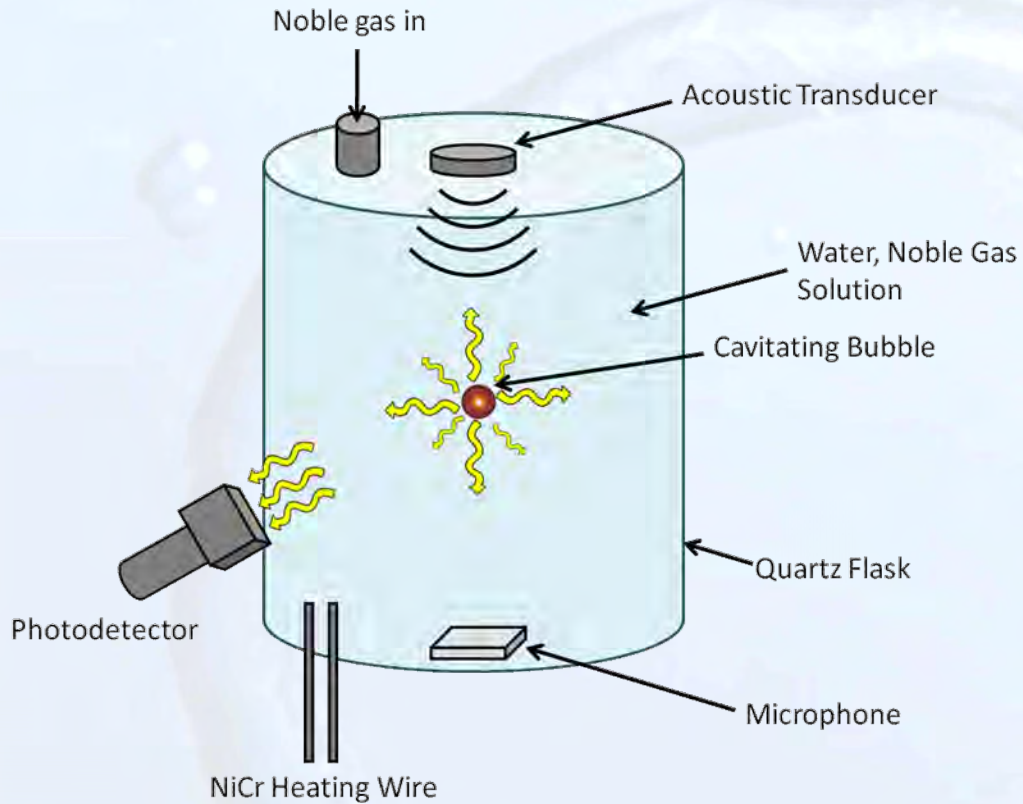

### Creation of negative pressure and observation of bubbles

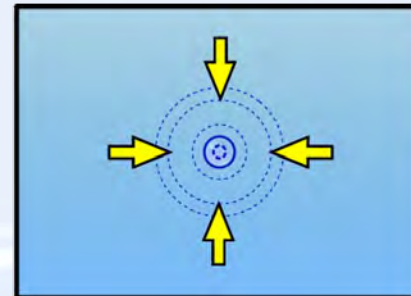

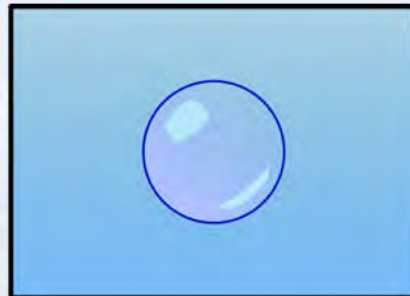

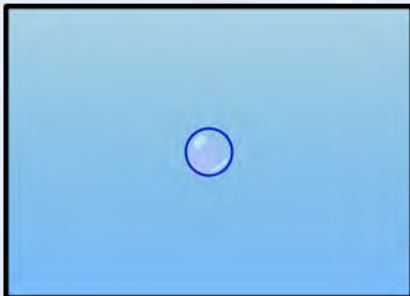

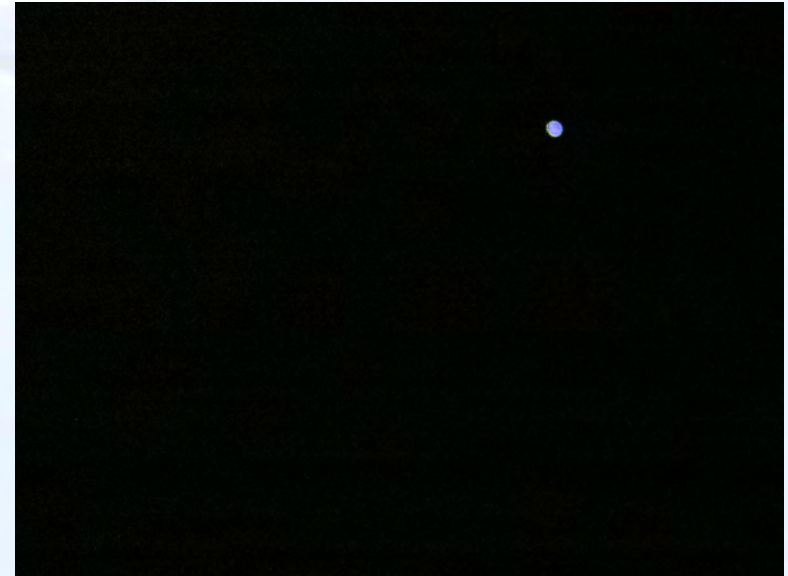

## Sonoluminescence

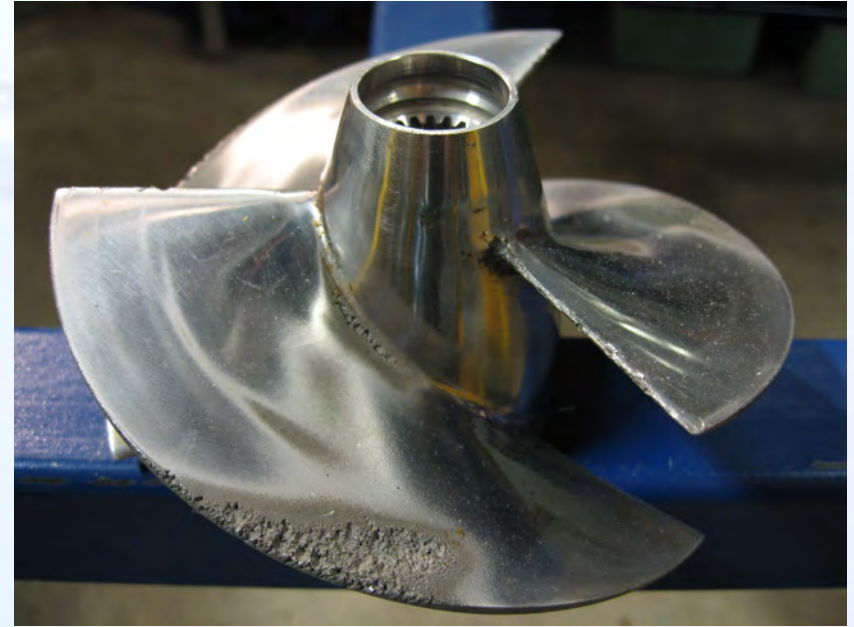

## Sonoluminescence in water

Collapsing bubbles are of great technical importance

Extracorporeal shockwave therapy using cavitation processes

### Acceleration of ions in constant field

→ constant drift velocity is reached

$$\bar{v}_d = \frac{q\mathcal{E}}{6\pi\eta r}$$

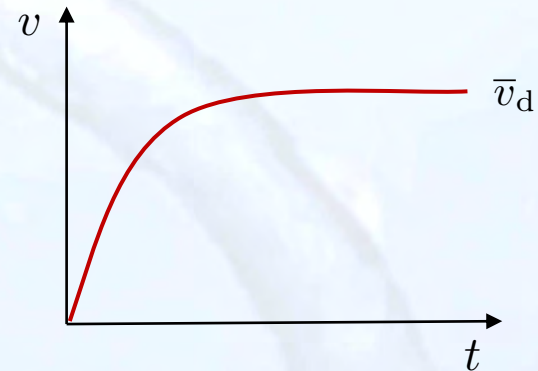

mobility:

$$\mu = \frac{\bar{v}_d}{\mathcal{E}} = \frac{q}{6\pi\eta r}$$

snowball (electrons  $4\pi$ )

Stokes law of  
viscos friction

constant electrical field  $\mathcal{E}$

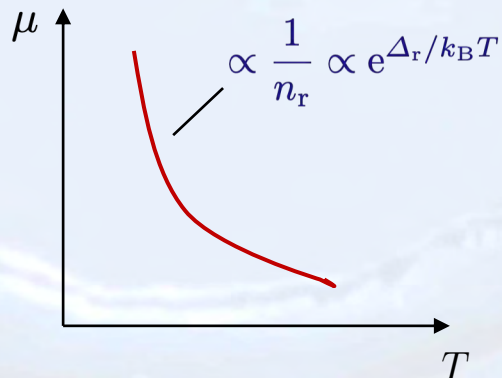

collision partners: **phonons**, **rotons**,  $^3\text{He}$ , ...  
impurities, which at some level are always present

**0.7 K < T < 1.8 K:** **rotons** should dominate however, **difficult** to **observe** because of other excitations / impurities

mobility for roton scattering

$$\mu \propto \frac{1}{\eta} \propto \frac{1}{\tau} \propto \frac{1}{n_r}$$

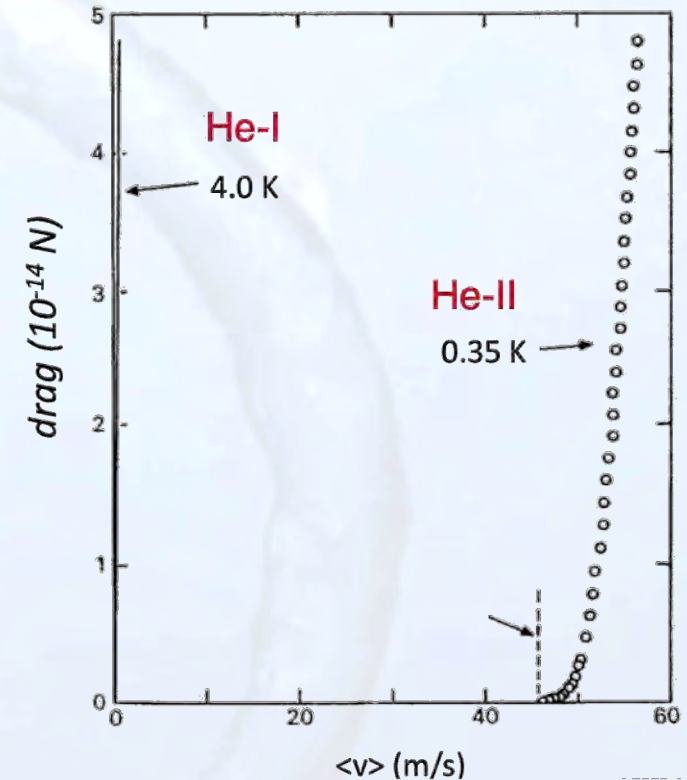

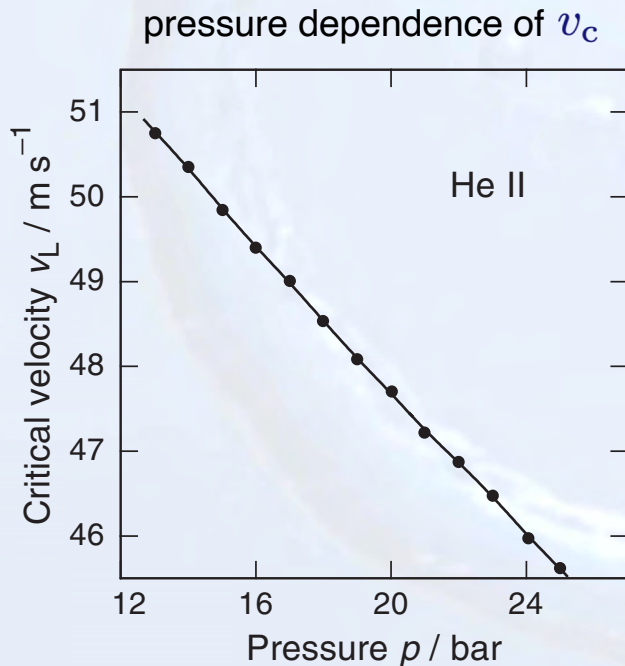

$$\eta = \frac{1}{3}\rho v^2 \tau = \frac{1}{3}\rho v \ell$$

in **ultra-pure** He-II **under pressure** ions can be accelerated up to **Landau velocity**

- ▶ **negative** ions **accelerated** in electric field under **high pressure**
- ▶ drag is measured by time-of-flight method
- ▶ in He-I: drag proportional to velocity
- ▶ in He-II: drag is **not observable** until critical velocity is reached

- ▶  $v_L \hat{=} v_c$  Landau velocity
- ▶ roton **pair** production
- ▶  $p \uparrow \longrightarrow v_L \downarrow$  since  $\Delta_r(p)$  decreases with pressure

$T < 0.3 \text{ K}$

no thermal rotons are excited

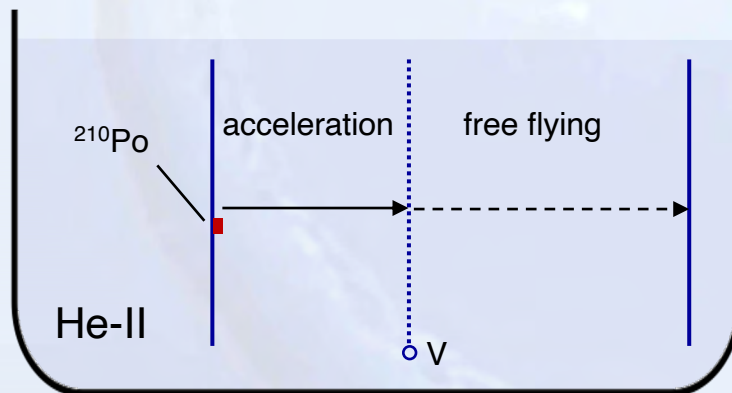

phonons **mean free path** becomes very large  $\longrightarrow$  several cm!

$$v_c \rightarrow 238 \frac{\text{m}}{\text{s}} ?$$

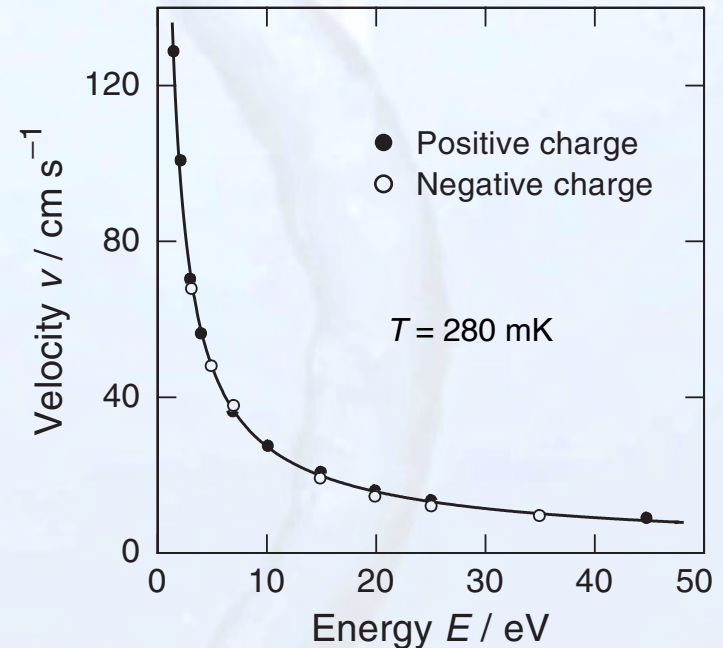

experimental answer: **no!**  $\bar{v}_d = 10 \dots 100 \text{ cm/s}$

in addition:  $\bar{v}_d$  **decreases** with **energy** of ions, which means  
it **decreases** with **accelerating** field

Experiment by Rayfield and Reif 1964

$\longrightarrow$  measurement of ion  
velocity by **time of flight**

explanation:

- **creation** of **vortex rings** and **trapping** of ions
- experiment **observes** motion of **vortex rings**

## vortex rings

kinetic energy of vortex ring: He-II  $\varrho \rightarrow \varrho_s$

$$E_{vr} = \int \frac{1}{2} \varrho_s v_s^2 dV = \frac{1}{2} \varrho_s \kappa^2 r \left[ \ln \left( \frac{8r}{a_0} \right) - \frac{7}{4} \right] \propto r$$

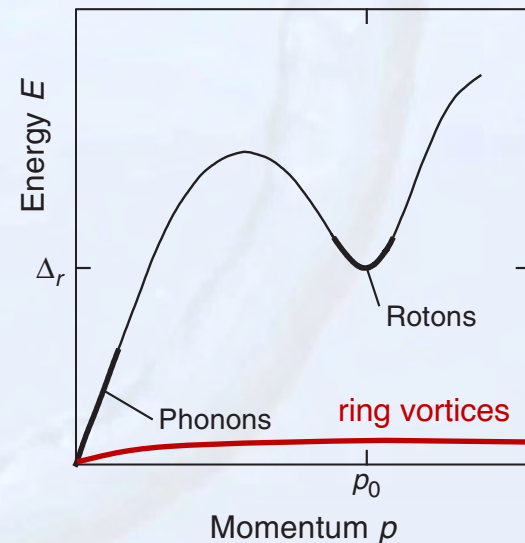

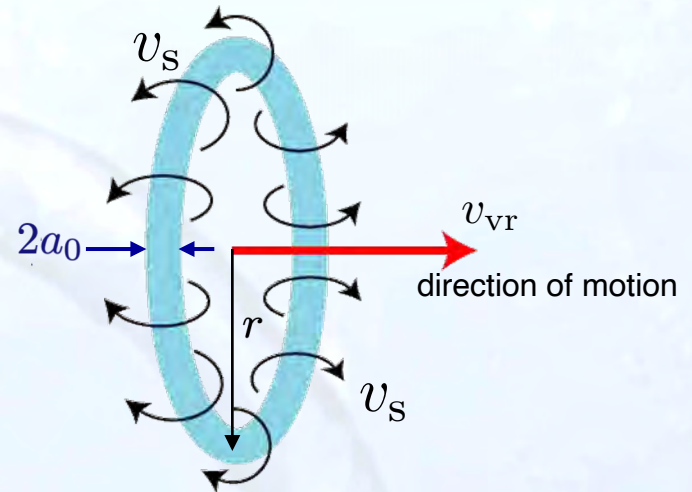

momentum of vortex ring  $p_{vr} = \pi \varrho_s \kappa r^2$

$$\rightarrow v_{vr} = \frac{\partial E}{\partial p_{vr}} = \frac{\kappa}{4\pi r} \left[ \ln \left( \frac{8r}{a_0} \right) - \frac{1}{4} \right]$$

$$\rightarrow p_{vr} \propto r^2 \propto E_{vr}^2 \quad \text{and} \quad v_{vr} \propto 1/E$$

$$\rightarrow \boxed{E_{vr} \propto \sqrt{p_{vr}}} \quad \begin{array}{c} \uparrow \\ \text{as observed} \end{array}$$

dispersion of vortex ring

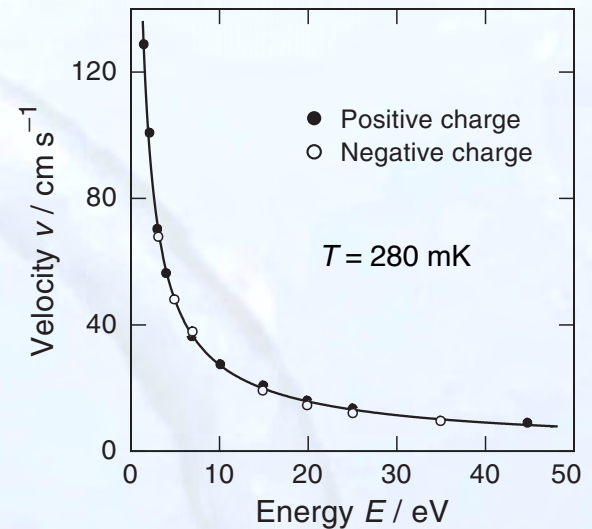

### Explanation of the experiment by Rayfield and Reif

- ▶ generation of vortex rings
- ▶ ions are captured by vortex ring
- ▶ field **increases kinetic energy** of vortex ring

$$v_{\text{vr}} \propto \frac{1}{r} \propto \frac{1}{E_{\text{vr}}}$$

- ▶ theory line with  $a_0 = 1.2 \text{ \AA}$

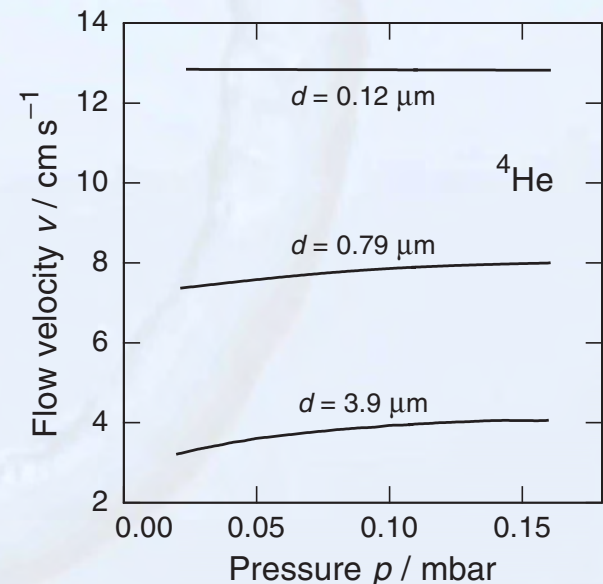

### let's revisit the flow experiments through capillaries

because of  $E_{\text{vr}} \propto \sqrt{p_{\text{vr}}}$ , **largest possible vortex** is has **minimal critical velocity**

for capillary with diameter  $d$

$$v_{\text{c, vr}} = \frac{\hbar}{m_4 d} \left[ \ln \left( \frac{4d}{a_0} \right) - \frac{1}{4} \right] \propto \frac{1}{d}$$

➡ **qualitative agreement** with flow experiments in capillaries

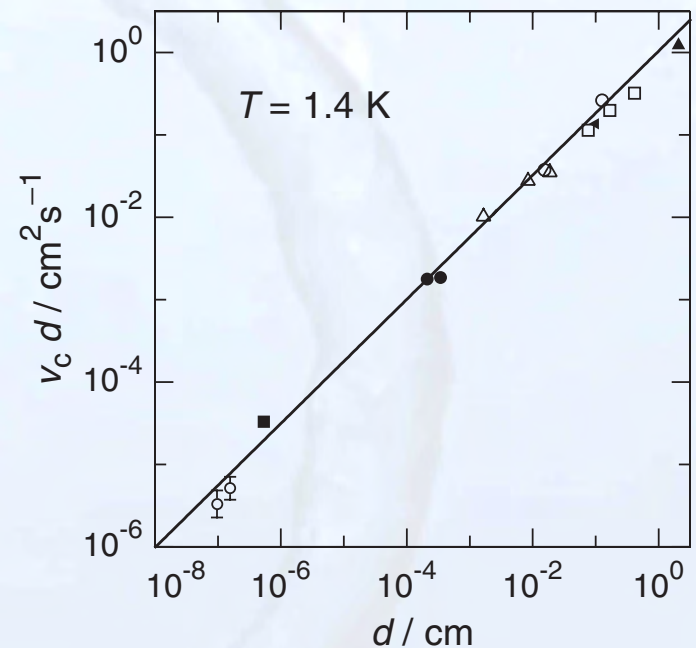

flow experiments to determine the critical velocity

how does the **critical velocity** depend on  $d$  ?

- ▶ plotted is:  $v_c d$  vs  $d$
- ▶ critical velocity  $v_c \propto d^{-1/4}$
- ▶ expected  $v_c \propto d^{-1}$
- ▶ reason is unknown

Properties near  $T_c$  are determined by quantities that go to **zero** like the **order parameter** and quantities that **diverge** like **susceptibilities**

**Landau theory** of continuous **phase transitions** (1937, 1965)

- ▶ idea: expansion of free energy in  $T$  in terms of the order parameter
- ▶ near  $T_c$  one should find the following laws with the reduced temperature  $t = (T - T_c)/T_c$

Quantity	Power Law	Critical Exponent
specific heat	$C_V \propto  t ^\alpha$	$\alpha = 0$
order parameter	$\Phi \propto  t ^\beta$	$\beta = 1/2$
susceptibility	$\chi \propto  t ^{-\gamma}$	$\gamma = 1$
correlation length	$\xi \propto  t ^{-\nu}$	$\nu = 1/2$

Landau type theories: – van der Waals theory for liquid – gas transition  
– Curie-Weiss theory of ferromagnetism  
– Ginzburg-Landau theory of superconductivity

**Problem:** fluctuations are not included, but they are increasingly important towards  $T_c$

→ every Landau-type theory breaks down near  $T_c$

### Ginzburg criterion

The condition under which a Landau-type theory holds is that fluctuations of the order parameter are small in comparison of the mean value of the order parameter

for He-II: coherence length is very small → Ginzburg criterion is "always" violated

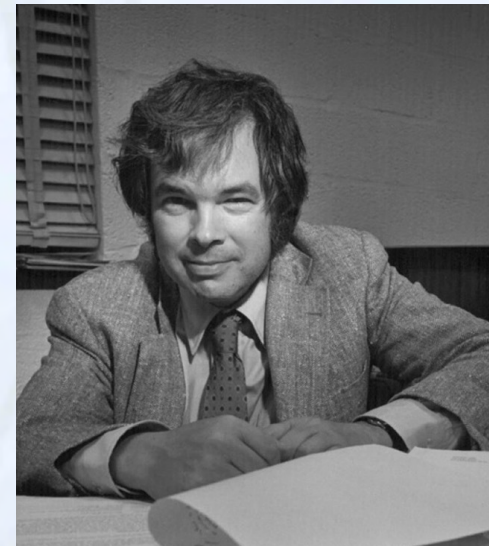

### Renormalization group

Despite of the **short-comings** of the Landau **universal theory** of **phase transitions**, it was realized that it is possible to assign **different** physical systems to **universality classes**, characterized by a **set of critical exponents**

The larger framework is: renormalization group and quantum field theory

different classes are defined by:

- dimension of system  $d$ ,
- degrees of freedom of order parameter  $n$ ,
- interaction length compared to coherence length

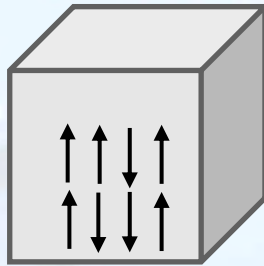

Kenneth G. Wilson

a few examples:

Ising 3 D

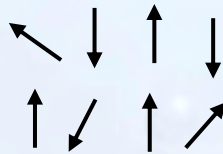

$$d = 3$$

$$n = 1$$

in this universality class liquid-solid transition fall as well

Heisenberg 2 D

$$d = 2$$

$$n = 3$$

at each lattice point each spin can point in 3 direction

x-y 3 D

He-II

superconductors

$$d = 3$$

$$n = 2$$

magnitude and phase of wave function

each universality class is described by a set of critical exponents and are connected by sum rules like  $\alpha + 2\beta + \gamma = 2$

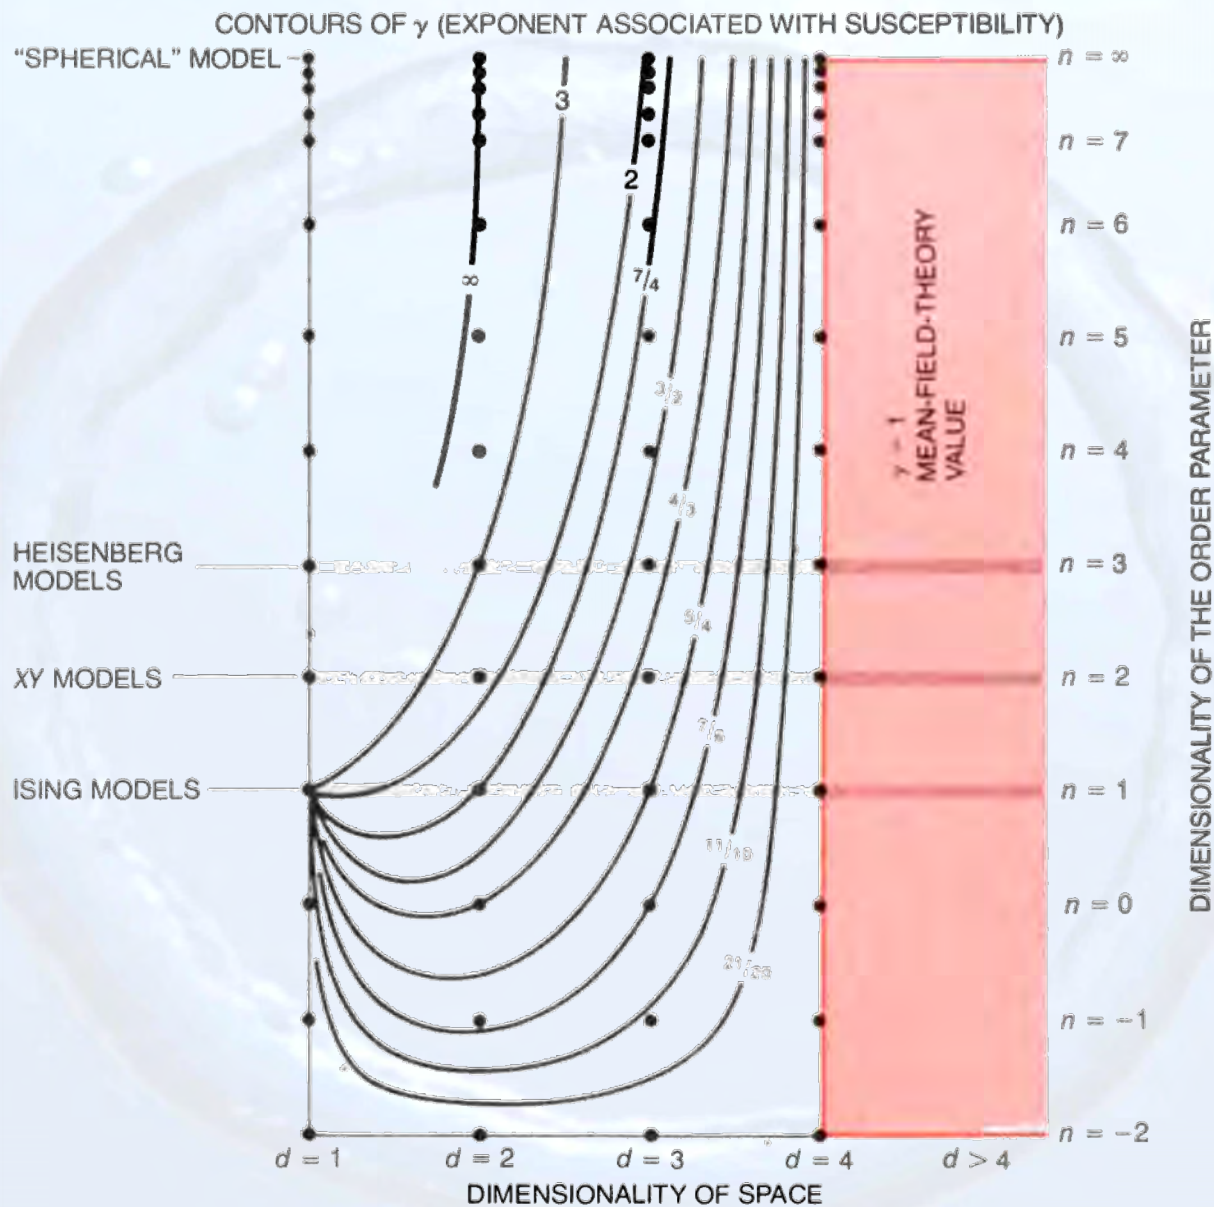

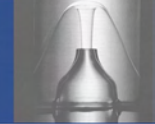

## 2.7 Critical Behaviour of He-II at $T_\lambda$

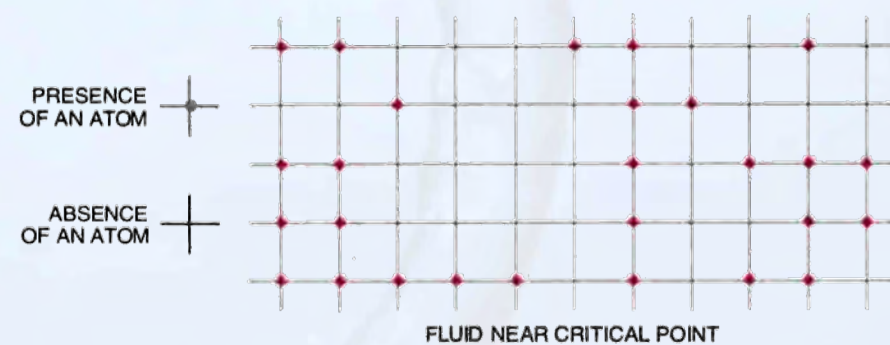

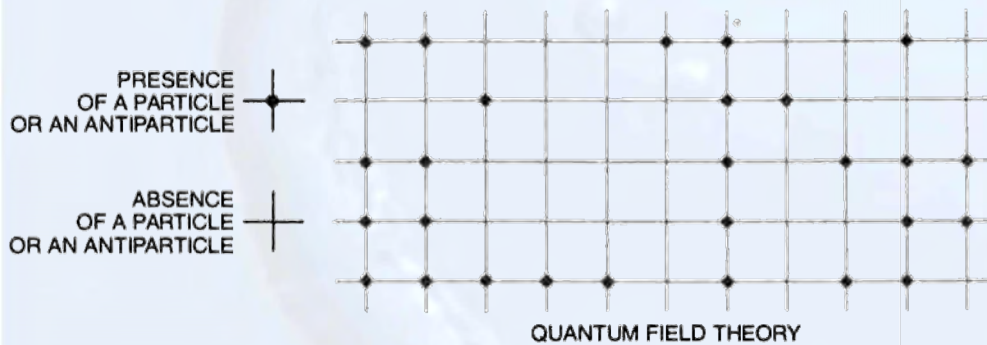

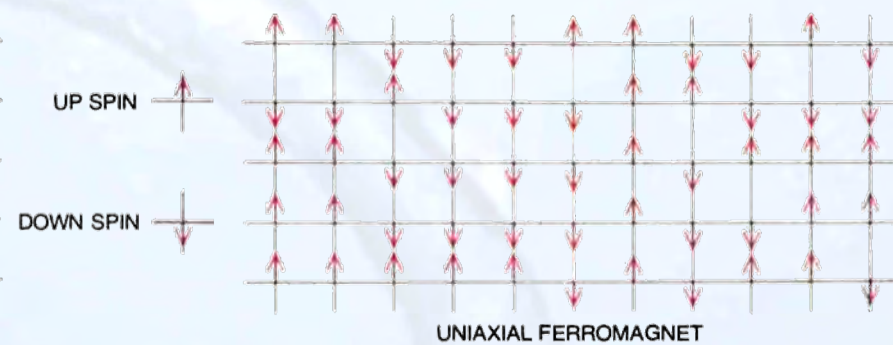

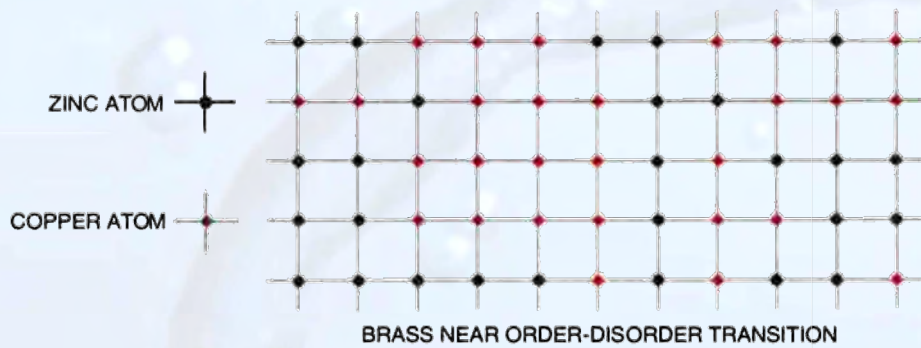

UNIVERSALITY CLASS		THEORETICAL MODEL	PHYSICAL SYSTEM	ORDER PARAMETER
$d = 2$	$n = 1$	Ising model in two dimensions	Adsorbed films	Surface density
	$n = 2$	XY model in two dimensions	Helium-4 films	Amplitude of superfluid phase
	$n = 3$	Heisenberg model in two dimensions		Magnetization
$d > 2$	$n = \infty$	"Spherical" model	None	
$d = 3$	$n = 0$	Self-avoiding random walk	Conformation of long-chain polymers	Density of chain ends
	$n = 1$	Ising model in three dimensions	Uniaxial ferromagnet	Magnetization
			Fluid near a critical point	Density difference between phases
			Mixture of liquids near consolute point	Concentration difference
			Alloy near order-disorder transition	Concentration difference
	$n = 2$	XY model in three dimensions	Planar ferromagnet	Magnetization
			Helium 4 near superfluid transition	Amplitude of superfluid phase
	$n = 3$	Heisenberg model in three dimensions	Isotropic ferromagnet	Magnetization
$d \leq 4$	$n = -2$		None	
	$n = 32$	Quantum chromodynamics	Quarks bound in protons, neutrons, etc.	

## 2.7 Critical Behaviour of He-II at $T_\lambda$

critical exponents expected for X-Y 3D model:

$$\alpha = -0.0146(8) \quad \leftarrow$$

$$\delta = 4.780(2)$$

$$\beta = 0.3485(2) \quad \leftarrow$$

$$\nu = 0.67155(27) \quad \leftarrow$$

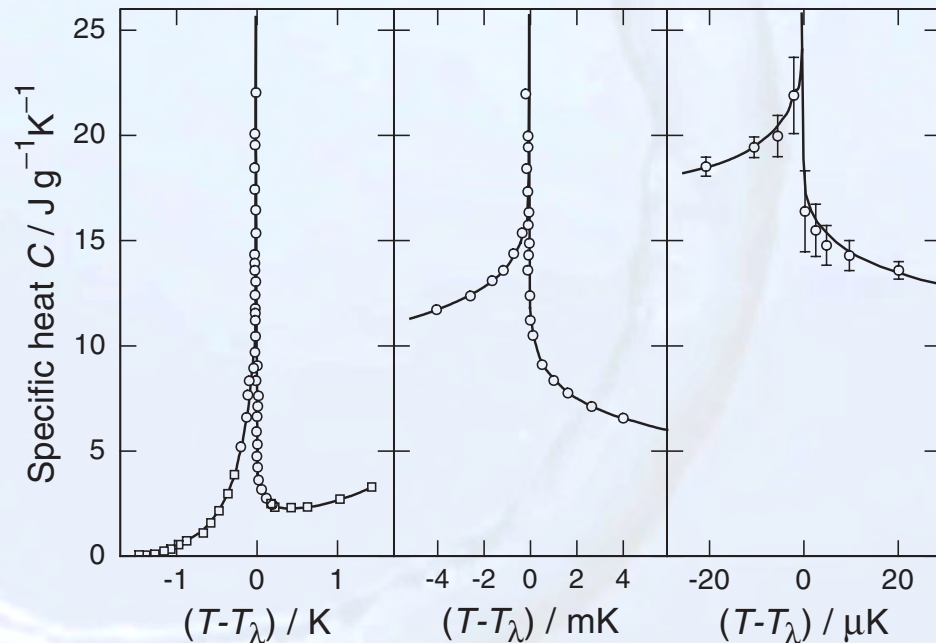

$$\gamma = 1.3177(5)$$

$$\eta = 0.0380(4)$$

### Experiments near $T_\lambda$

a) specific heat

scale going from K to  $\mu\text{K}$

power law in the vicinity of  $T_\lambda$  ?

data plotted as  $C_V$  vs  $\log t = \log |T/T_\lambda - 1|$

data can be approximated by  $C_V \propto \log t$

logarithmic divergences?

comparison with RGT

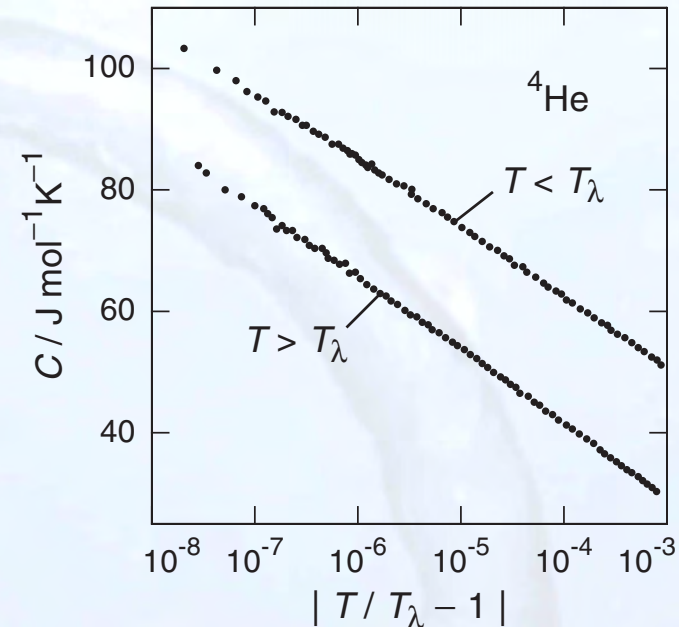

expected scaling for He-II

$$C = B + A \frac{t^{-\alpha}}{\alpha} (1 - D \sqrt{t}) \quad A, B \text{ and } D \text{ are constants}$$

with critical exponent expected  $\alpha = -0.146(8)$

→ expansion in  $\alpha$   $t^{-\alpha} = e^{-\alpha \ln t} \approx 1 - \alpha \ln t$  expansion justified because of **small**  $\alpha$

experimental result  $\alpha \approx -0.013 \pm 0.003$

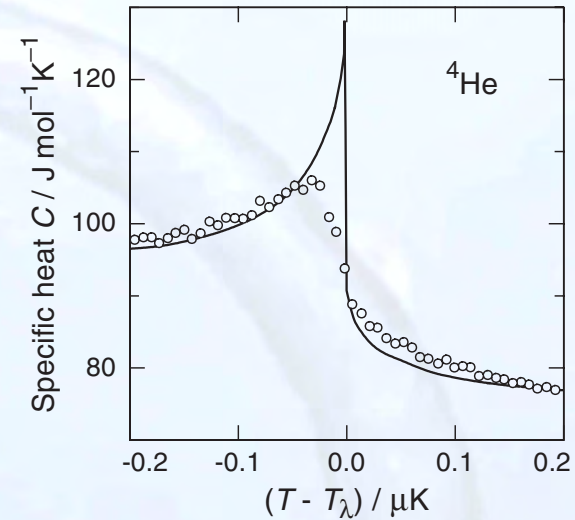

Higher precision experiments near  $T_\lambda$  are needed

measurement on earth

Problems:

gravitation  $\longrightarrow$  level height dependence

walls of vessel  $\longrightarrow$  first layer solid and healing length diverges with diverges near  $T_\lambda$  with  $\xi = \xi_0 t^{-\nu}$  with  $\nu = 0.67155(27)$

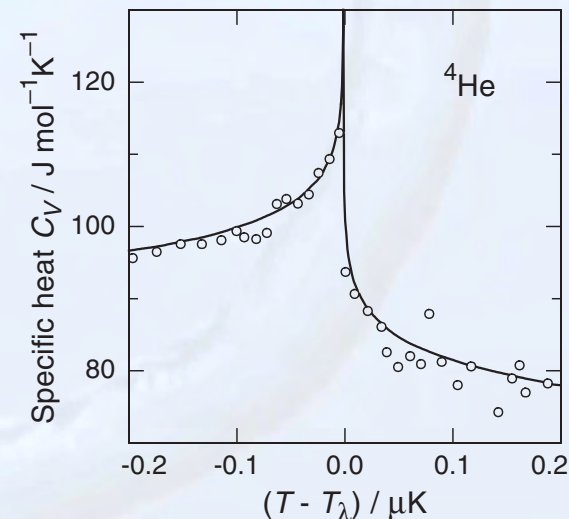

measurement on space shuttle

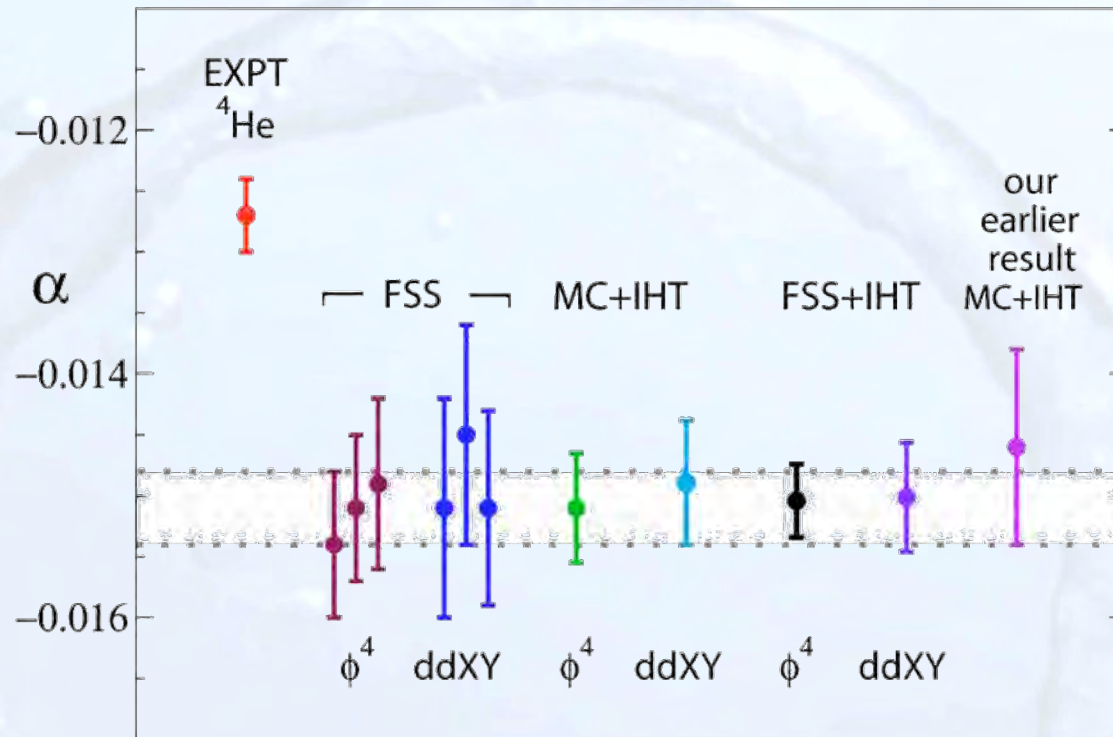

Problems:

cosmic rays  $\longrightarrow$  time varying background (heating of thermometer)

Data shown, after sophisticated analysis

$\longrightarrow$  still somewhat noisy

comparison between space shuttle data and different calculations of  $\alpha$

➡ discrepancy between data and theory outside error bars: reason unknown

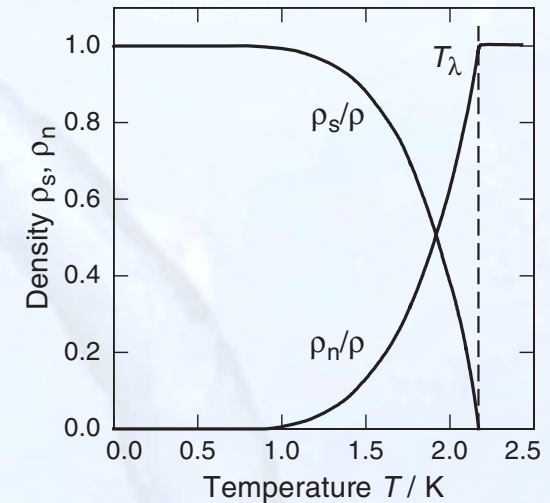

### b) Order parameter

$$\psi(\mathbf{r}) = \psi_0 e^{i\varphi(\mathbf{r})} \longrightarrow \text{amplitude of wave function} \quad \Psi_0 = \sqrt{\varrho_s}$$

expected:

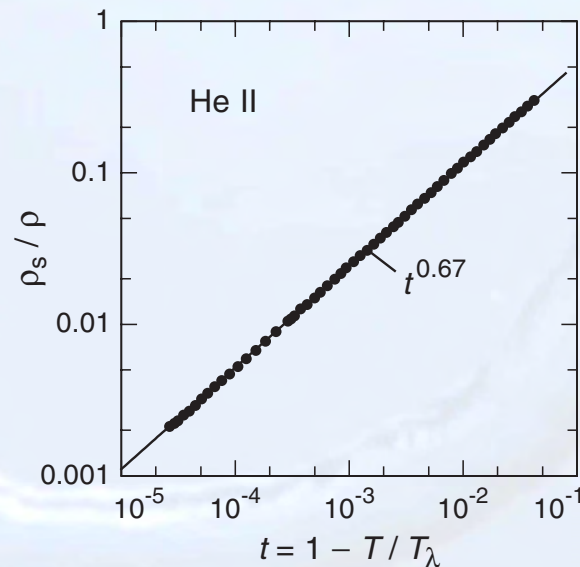

$$\varrho_s = t^{2\beta} \quad \text{with} \quad \beta = 0.3485(2)$$

determined with **second sound**

$$\varrho_s = t^{0.67}$$

**→** excellent agreement

### c) Healing length

again, **second sound** measurements  
and measurements on **thin films**

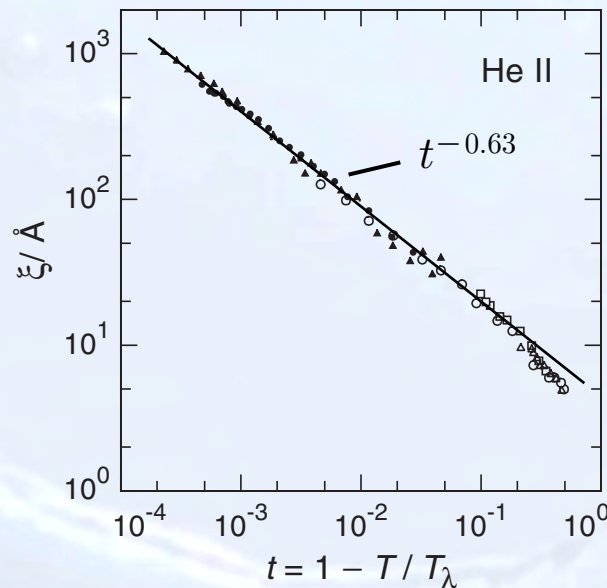

expected:

$$\xi = \xi_0 t^{-\nu} \quad \text{with} \quad \nu = 0.67155(27)$$

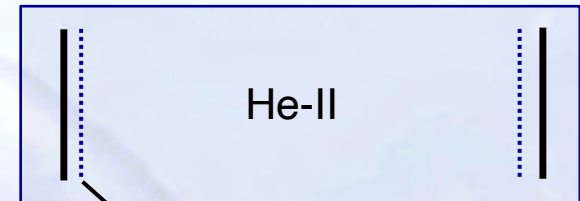

$$\xi_0 = 2.8 \pm 0.5 \text{ \AA}$$

$$\nu = 0.63$$

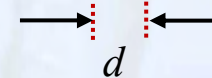

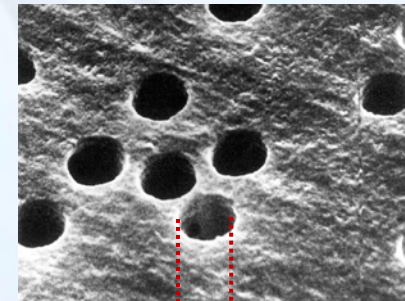

→ excellent agreement

Helmholtz resonator

Nuclepore filters

second sound vanishes  
for  $\xi > d$
